

Lesson 52 Header design

First thing to keep in mind, the titles in the header should be stored in the website class not header website. Hence, the page website class can access these titles.

The header could be a table with an image or without as u like.

But to specify the css code for the table only in the header, you got to add a class name for the table, and then call that class in the css code, like this :

```
table . headertable {
.....
.....
}
```

As you know we need html code for the header and css code,
So don't forget to add in the class of header in private two
string attributes , one for the html code and the other one for
the css.

in the public section, you will add 4 methods :

- void generate code () // generate the code of the html and css
- void choose header()
- String getHtml()//returns the html code
- String getCss()//returns the css code
